OPSTRACK

Recurring Task Tracking & Escalation Automation

Project Overview

OpsTrack is a proposed Google Sheets and Google Apps Script prototype for managing recurring operational tasks, capturing completion evidence, tracking overdue work, and notifying the appropriate managers. It is prepared for the **Allo Innoware AI Operations Manager assignment** and follows the requirements described in the assignment brief.

> **Project objective**
> **Create one clear place for employees to update recurring tasks and for managers to monitor pending work, acknowledge alerts, and escalate unresolved overdue tasks.**

Executive Summary

Recurring tasks can be difficult to manage when due dates, evidence, follow-ups, and escalation messages are spread across separate conversations or manual trackers. OpsTrack brings these activities into a structured spreadsheet workflow. A task is assigned an owner, recurrence interval, next due date, and required proof type. Employees submit proof in a single console and mark the task complete. The automation is designed to validate the proof, record a completion event, advance the next due date, and retain a history of activity.

For overdue work, a scheduled Apps Script check is designed to send a manager notification, record the alert, and escalate the issue to leadership if it remains unresolved beyond the configured SLA. Alert deduplication is intended to prevent repeated notifications for the same task cycle. The package is a prototype that must be installed, authorized, and tested in a Google account before it can be represented as a live, verified system.

Key capabilities

- **Recurring schedules:** daily, every 7 days, every 15 days, and every 30 days.
- **Single completion console:** employees provide a ticket ID for portal tasks or evidence for the daily update.
- **Audit trail:** completion log captures task cycle, owner, actor information when available, timestamp, and proof.
- **Overdue workflow:** manager alerts, acknowledgement notes, and leadership escalation after the configured delay.
- **Alert controls:** cycle-based deduplication and closure of active alerts after completion.

1. Case Study

Business problem

The assignment describes a small team responsible for operational work that repeats on different schedules. Without a consistent tracking process, an employee may overlook a due task, a manager may not have a current view of pending work, and evidence of completion may be difficult to find. Manual reminders can also create duplicate messages without making the task status clearer.

Solution design

OpsTrack uses Google Sheets as the shared operating interface and Google Apps Script as the automation layer. The design separates task configuration, employee updates, completion history, alert history, and settings into dedicated tabs.

Component	Purpose
Task_Master	Stores task owner, frequency, due date, required proof, and cycle details.
Employee_Console	Provides the main place to enter proof and mark a task complete; includes manager acknowledgement fields.
Completion_Log	Maintains a record of task completion, cycle, timestamp, and submitted evidence.
Alerts_Log	Tracks manager alerts, leadership escalations, acknowledgements, and resolution details.
Config	Holds recipient and SLA configuration for the prototype.

End-to-end workflow

1. A task is configured with an assigned employee, recurrence interval, next due date, and proof requirement.
2. The employee enters a ticket ID for portal work or a short update / WhatsApp evidence reference for the daily task.
3. When completion is submitted, the script checks for the required proof and records the completed task cycle.
4. The next due date and cycle number are advanced according to the task's configured recurrence.
5. An overdue scan checks outstanding tasks and sends a manager email when the configured overdue condition is met.
6. The manager records an acknowledgement and optional note. If the task remains unresolved after the SLA, a leadership escalation is sent.
7. Alert records are intended to be deduplicated by task cycle and alert type; completion closes active alerts for that cycle.

Proposed service-level agreement (SLA)

Control	Proposed behavior
Manager notification	Send on the first scheduled SLA scan after the task becomes overdue; an hourly trigger is approximate, not exact.
Resolution window	Allow 24 hours from the first manager alert for the task to be resolved.
Leadership escalation	Escalate after the configured 24-hour delay if the task is still unresolved.
Duplicate prevention	Use task ID, cycle number, and alert type to prevent repeat alerts for the same cycle.

2. Validation Plan & Limitations

The prototype should be demonstrated with dummy tasks and test inboxes before being shared for evaluation. The following checks align with the assignment's expected behavior.

Test	Expected result
Recurring cycle	Completing a 7-day task advances its next due date by seven days and increments the cycle.
Single-point completion	Proof and completion are submitted from the employee console and one completion record is created.
Daily task proof	The daily task accepts a non-ticket proof entry, such as a short update or evidence reference.
Manager alert	An overdue dummy task creates one manager alert and sends an email to the configured test recipient.
Acknowledgement	Manager acknowledgement and note are captured in the relevant records.
Leadership escalation	An unresolved overdue task escalates after the configured delay.
Deduplication	Repeated SLA scans do not create duplicate alerts for the same task cycle.

Important limitations

- This deliverable documents a prototype design and starter implementation. It is not proof that the system has been deployed or successfully tested in the user's Google account.
- Google Apps Script time-driven triggers run approximately and may not fire at an exact minute; confirm the SLA expectations with the evaluator.
- The daily task's WhatsApp evidence is supplied by the employee. The prototype does not independently access or verify WhatsApp content.
- Google may not expose the active user's email in every authorization context; the identity field may fall back to the assigned employee label.
- The prototype focuses on the current cycle for each task. If multiple missed cycles must each be tracked independently, a separate cycle-instance table would be needed.
- Test mode does not itself guarantee email suppression. Configure test inboxes before running alert tests or enabling automation.

3. Summary

OpsTrack addresses the core operational need in the Allo Innoware assignment: recurring work should be visible, easy to update, supported by completion evidence, and followed up through a consistent overdue process. Google Sheets provides a familiar shared interface, while Apps Script is intended to automate proof validation, completion logging, recurrence updates, manager notifications, acknowledgements, and escalation.

The main value of the design is process consistency. Employees use one console instead of updating several places, managers have a structured record of pending tasks and alerts, and leadership escalation follows a defined rule rather than relying only on manual reminders. The proposed SLA and test plan make the expected behavior explicit and reviewable.

4. Conclusion

OpsTrack provides a practical foundation for recurring task management and escalation using tools that are accessible and familiar to many operations teams. By combining a task master, a single employee console, completion and alert logs, and configurable SLA rules, the prototype is designed to improve visibility, accountability, and the consistency of follow-up.

Before production use, the spreadsheet and Apps Script must be deployed under an authorized Google account, recipients and SLA settings must be confirmed, and each test case must be executed using dummy tasks and controlled email inboxes. The team should also confirm how daily proof will be accepted, whether manager acknowledgement is mandatory, and whether the proposed 24-hour escalation window meets operational expectations.

Once deployed and validated, OpsTrack can serve as a lightweight operations workflow that reduces dependence on manual tracking and makes overdue tasks easier to identify and resolve. Its effectiveness should be evaluated through test results, alert accuracy, duplicate prevention, and feedback from employees and managers.

> **Final takeaway**
> **OpsTrack is designed to turn recurring task tracking from a manual reminder process into a structured workflow with proof, traceability, manager visibility, and SLA-based escalation. Its readiness for real use depends on deployment, authorization, and successful completion of the validation checklist.**

Prepared for the Allo Innoware AI Operations Manager assignment. This report describes the intended prototype and its proposed workflow; it does not claim that deployment or live email testing has already been completed.
